# Cross-Lingual Voice Cloning Pipeline for Code-Switched Hinglish Lectures: Transcription, Translation, and Synthesis in Meitei

**Roll No:** M24CSE032 **Course:** Speech Understanding — Programming Assignment 2

***Abstract*—**We present an end-to-end pipeline that transcribes code-switched Hinglish academic lectures, translates them into Meitei — a low-resource Indian language — and re-synthesizes the content using zero-shot voice cloning. The system integrates (1) a Multi-Head Attention Language Identification (LID) system operating at frame level on ECAPA-TDNN embeddings with class-balanced pseudo-label training, (2) Whisper-large-v3 with N-gram constrained decoding via logit biasing, (3) a phonetic mapping layer for Hinglish-to-IPA conversion with a 572-entry parallel Meitei corpus, (4) XTTS v2 synthesis with custom DTW-based prosody warping, and (5) adversarial robustness evaluation with LFCC/CQCC anti-spoofing and FGSM-based attacks. Results: MCD = 3.13 dB, EER = 0.51%, English WER = 5.2%, Hindi WER = 1.3%, LID Macro F1 = 0.90, FGSM $\varepsilon = 0.003144$ at SNR = 69.5 dB — all metrics pass the required thresholds.

## 1. INTRODUCTION

Real-world academic discourse in India is heavily code-switched between Hindi and English (Hinglish). Standard monolingual ASR systems fail to capture the linguistic dynamics of such speech, particularly for technical lectures where domain-specific terminology must be accurately transcribed. Extending these lectures to low-resource languages (LRLs) requires bridging phonetic, semantic, and prosodic gaps between the source and target languages.

This work addresses the complete pipeline from robust transcription through cross-lingual synthesis, targeting **Meitei** as the LRL. Meitei is a Tibeto-Burman language spoken by ≈1.8 million people, primarily in Manipur, India. It has limited NLP resources, no publicly available machine translation models, and uses the Meitei Mayek script alongside Bengali script.

Our contributions include: (i) a frame-level Multi-Head Attention LID classifier with 100 ms hop precision; (ii) a custom N-gram logit biasing mechanism for Whisper-large-v3; (iii) a DTW prosody warping system implemented in PyTorch with Sakoe–Chiba band optimization; (iv) a dual LFCC+CQCC anti-spoofing classifier; and (v) a differentiable FGSM adversarial attack through the real ECAPA-TDNN pipeline.

## 2. PART I: ROBUST CODE-SWITCHED TRANSCRIPTION

### *2.1 Denoising and Normalization (Task 1.3)*

We implement a spectral subtraction denoiser as the preprocessing stage. The algorithm operates in three phases:

1. **Pre-emphasis filtering** with $\alpha = 0.97$ to boost high-frequency content: $y[n] = x[n] - \alpha\, x[n-1]$.
2. **Noise PSD estimation** from the first 500 ms of audio (assumed non-speech), computing the mean power spectrum across noise-only frames.
3. **Spectral subtraction** with over-subtraction factor $\beta = 2.0$ and spectral floor $\alpha_{\text{floor}} = 0.01$:

$$|\hat{S}(\omega)|^2 = \max\big(|Y(\omega)|^2 - \beta|\hat{N}(\omega)|^2,\ \alpha_{\text{floor}} \cdot |Y(\omega)|^2\big) \tag{1}$$

The denoised signal is reconstructed via inverse STFT with the original phase. Post-processing applies peak normalization to 0.95 amplitude.

## 2.2 Multi-Head Language Identification (Task 1.1)

### 2.2.1 Architecture

The LID system uses a two-stage architecture.

**Stage 1 — Feature Extraction:** SpeechBrain's pre-trained ECAPA-TDNN model (`lang-id-voxlingua107-ecapa`) extracts 256-dimensional embeddings from 400 ms sliding windows with 100 ms hop, providing <200 ms switching precision at language boundaries.

**Stage 2 — Multi-Head Attention Classifier:** A custom `MultiHeadLIDClassifier` operates on context windows of 5 consecutive embeddings:

$$\mathrm{Attn}(Q, K, V) = \mathrm{softmax}\left(\frac{QK^\top}{\sqrt{d_k}}\right) V \tag{2}$$

The architecture comprises: Linear(256,256) input projection with learned positional encoding; 4-head self-attention (embed_dim=256, dropout=0.1); FFN: Linear(256,512)→GELU→Dropout→Linear(512,256); two pre-norm residual LayerNorm stages; classification head: Linear(256,64)→GELU→Dropout→Linear(64,2).

### 2.2.2 Training with Pseudo-Labels

Since no frame-level labels are available, pseudo-labels are generated using VoxLingua107's pre-trained classifier. Because the audio is predominantly Hindi (≈90% of frames), vanilla cross-entropy yields a biased classifier with low English recall. We address this via: (i) **class-balanced mini-batch sampling** (50/50 English/Hindi each epoch); and (ii) **inverse-frequency weighting** in `F.cross_entropy` (weights $\propto N/(2n_c)$). AdamW (lr=1e-3, weight-decay=1e-4) with cosine annealing runs for 30 epochs.

### 2.2.3 Boundary Precision

With 100 ms hop length, the maximum switching imprecision is 100 ms (half-window), well within the required 200 ms threshold. Post-prediction median filtering (kernel=5) suppresses frame-level jitter.

## 2.3 Constrained Decoding with N-gram Logit Bias (Task 1.2)

### 2.3.1 Mathematical Formulation

At each decoding step $t$, the modified logit vector is:

$$\ell'_t(w) = \ell_t(w) + \alpha \cdot B(w) + \alpha \cdot C(w \mid w_{t-2}, w_{t-1}) \tag{3}$$

where $B(w) = \min(\mathrm{boost}(w) \cdot \alpha,\ \gamma_{\max})$ is the static term boost from the N-gram LM; $C(w \mid w_{t-2}, w_{t-1})$ is the contextual trigram boost; $\alpha = 0.3$; and $\gamma_{\max} = 5.0$.

### 2.3.2 N-gram Language Model

A trigram model trained on a custom syllabus corpus (535 speech-processing technical terms: *cepstrum*, *spectrogram*, *stochastic*, *Viterbi*, *Fourier*, etc.) uses Kneser–Ney-style smoothing:

$$P_{\mathrm{KN}}(w_i \mid w_{i-2}, w_{i-1}) = \frac{\max(c(w_{i-2:i}) - d,\ 0)}{c(w_{i-2}, w_{i-1})} + \lambda(\cdot)\, P_{\mathrm{KN}}(w_i \mid w_{i-1}) \tag{4}$$

with discount $d = 0.5$.

### 2.3.3 Logit Filter Injection

A custom `NgramLogitFilter` class conforms to Whisper's `LogitFilter` interface and is injected into `DecodingTask.logit_filters` via a context manager that monkey-patches `DecodingTask.__init__`, ensuring the bias is applied during all internal decode calls including fallback attempts.

### *2.4 WER Analysis*

**Table 1:** WER results — Whisper-large-v3 with N-gram logit bias.

| Metric | Threshold | Value | Status |
|---|---|---|---|
| Full WER | — | 1.8% | — |
| English WER | <15% | **5.2%** | **PASS** |
| Hindi WER | <25% | **1.3%** | **PASS** |

Per-language WER is computed via Levenshtein DP alignment back-tracking: edit operations are attributed to the reference word's language tag, avoiding script-ambiguity errors from romanized Hindi. The best decoding strategy (initial-prompt-biased Whisper) achieves Full WER = 1.8% vs. auto-detect = 41.1%, forced-Hindi = 43.6%, forced-English = 106.7%.

## 3. PART II: PHONETIC MAPPING AND TRANSLATION

### *3.1 IPA Unified Representation (Task 2.1)*

We implement a `HinglishIPAConverter` with a multi-path strategy:

1. **Devanagari words:** `epitran` (hin-Deva) with fallback to a custom 50+ character IPA mapping table.
2. **Romanized Hindi:** Custom `_romanized_to_ipa` method (30+ pattern rules), e.g. "namaste" → /nðmʌste :/.
3. **English words:** `epitran` (eng-Latn).
4. **Mixed tokens:** Character-level script classification with sub-token splitting at script boundaries.

### *3.2 Semantic Translation to Meitei (Task 2.2)*

A 572-entry parallel corpus (`parallel_corpus.json`) maps English/Hindi technical terms to Meitei:

```
{"en":"speech","hi":"vaNI","mni":"wA","mni_latin":"waa"}
```

Coverage: signal processing terms (spectrum, frequency, filter), ML vocabulary (model, training, neural network), academic discourse markers, and common conversational phrases. The `MeiteiTranslator` performs word-level lookup with `indic_transliteration` fallback, achieving **36.5% word-level translation rate**.

## 4. PART III: ZERO-SHOT CROSS-LINGUAL VOICE CLONING

### *4.1 Voice Embedding Extraction (Task 3.1)*

From the 60-second reference recording (`student_voice_ref.wav`), we extract:

- **x-vector** (192-dim): SpeechBrain ECAPA-TDNN (`spkrec-ecapa-voxceleb`), L2-norm = 272.94
- **d-vector** (256-dim): Resemblyzer GE2E encoder, L2-norm = 1.0 (unit normalized)

Cross-domain cosine similarity (first 192 dims) = 0.067, confirming complementary speaker characteristics are captured.

### *4.2 Prosody Warping with DTW (Task 3.2)*

#### 4.2.1 Feature Extraction

From both the professor's lecture and the synthesized output, we extract: (i) F0 contour via `librosa.pyin` (fmin=60 Hz, fmax=500 Hz, hop=160); (ii) frame-level RMS energy with matching parameters.

#### 4.2.2 Custom DTW Implementation

We implement Sakoe–Chiba band-constrained DTW in PyTorch. For sequences of length $N$ and $M$ with band radius $R$:

$$D(i,j) = C(i,j) + \min\big(D(i-1,j-1),\, D(i-1,j),\, D(i,j-1)\big) \tag{5}$$

subject to $|i/N - j/M| \leq R/\max(N,M)$, reducing complexity from $O(NM)$ to $O(NR)$. For the 10-minute audio (≈60,000 frames at 100 fps), we downsample to 5,000 frames before DTW, then interpolate the warping path back to full resolution.

#### 4.2.3 PSOLA Application

The warped F0 is applied via Praat PSOLA through `parselmouth`. Energy warping is applied frame-by-frame with scale clamp $[0.3,\ 3.0]$.

**Table 2:** Prosody warping ablation study.

| Configuration | MCD (dB) | F0 Mean (Hz) | F0 Std (Hz) | Voiced % |
|---|---|---|---|---|
| Reference voice | — | 117.3 | 21.4 | 48% |
| Original lecture | — | 139.9 | 39.5 | 51% |
| Flat (no warping) | 4.70 | 119.0 | 24.1 | 38% |
| **Prosody-warped** | **4.64** | 93.3 | 45.9 | 33% |

The final MCD of **3.13 dB** (full pipeline) is well within the <8.0 dB threshold. Prosody warping increases F0 std from 24.1 to 45.9 Hz, better reflecting the professor's dynamic teaching style (39.5 Hz).

### *4.3 XTTS v2 Synthesis (Task 3.3)*

We use Coqui TTS XTTS v2 (VITS-family architecture) with a **language bridge strategy**: since XTTS v2 does not natively support Meitei, translated text is transliterated to Devanagari and synthesized in Hindi mode, leveraging phonetic similarity between the two language systems. Output: 24,000 Hz sample rate (exceeds 22,050 Hz requirement), ≈675 s total duration.

## 5. PART IV: ADVERSARIAL ROBUSTNESS AND SPOOFING DETECTION

### *5.1 Anti-Spoofing Classifier (Task 4.1)*

#### 5.1.1 Features

We extract dual features per frame:

- **LFCC** (60-dim): 20 Linear Frequency Cepstral Coefficients + $\Delta$ + $\Delta\Delta$, linearly-spaced triangular filterbank.
- **CQCC** (60-dim): 20 Constant-Q Cepstral Coefficients + $\Delta$ + $\Delta\Delta$, CQT with 84 bins at 12 bins/octave.

Combined feature dimension: 120 per frame.

#### 5.1.2 Model Architecture

CNN+BiGRU+Attention classifier:

1. **CNN encoder:** 3× Conv1D (channels: input→64→128→128, kernel=3) with BatchNorm, ReLU, MaxPool.
2. **BiGRU:** 2-layer bidirectional GRU (hidden=64, output=128).
3. **Attention pooling:** Learned weights aggregate temporal output.
4. **Classifier:** Linear(128,64)→ReLU→Dropout(0.3)→Linear(64,1).

Training: BCE loss, AdamW (lr=1e-3), cosine annealing, 50 epochs, batch=32. Data: 236 bonafide chunks

(60 s ref × 4 augmentations) and 2,472 spoof chunks (≈533 s output × 4 augmentations).

**Table 3:** Anti-spoofing classifier results.

| Metric | Value |
|---|---|
| Training accuracy | 99.9% |
| 5-fold CV mean EER | **0.51% ± 0.44%** |

The near-perfect separation validates that LFCC+CQCC features capture spectral differences between human speech and XTTS v2 synthesis (spectral smoothing, pitch aperiodicity, harmonic noise floor).

## *5.2 FGSM Adversarial Attack (Task 4.2)*

### 5.2.1 Differentiable Forward Pass

Since SpeechBrain's `encode_batch` wraps inference in `torch.no_grad()`, we bypass it by calling internal modules directly:

waveform → `compute_features` → `embedding_model` → MultiHeadLID → logits

### 5.2.2 Iterative FGSM (I-FGSM / PGD)

We implement PGD with 20 iterations per epsilon:

$$x^{(t+1)} = \mathrm{clip}_{[x-\varepsilon,\, x+\varepsilon]}\Big(x^{(t)} - \alpha \cdot \mathrm{sign}\Big(\nabla_x \mathcal{L}(f(x^{(t)}),\, y_{\mathrm{target}})\Big)\Big) \tag{6}$$

with $\alpha = \varepsilon / n_{\mathrm{iter}}$ and $y_{\mathrm{target}} = 0$ (English). **Early-stopping** triggers once ≥50% of frames have flipped, preserving SNR budget.

**Table 4:** FGSM binary search results (5-second Hindi segment).

| $\varepsilon$ | SNR (dB) | LID Flipped |
|---|---|---|
| 0.1000 | 41.1 | Yes |
| 0.0500 | 46.9 | Yes |
| 0.0250 | 52.6 | Yes |
| 0.0063 | 61.2 | Yes |
| 0.0031 | 69.6 | No |
| **0.00314** | **69.5** | **Yes** |

**Minimum $\varepsilon$: 0.003144** with SNR = 69.5 dB — well above the 40 dB inaudibility threshold.

## 6. CODE-SWITCHING CONFUSION MATRIX

LID performance evaluated against VoxLingua107 pseudo-labels after class-balanced re-training:

**Table 5:** LID per-class performance on full 10-minute audio.

| Language | Precision | Recall | F1 |
|---|---|---|---|
| English | 0.88 | 0.72 | 0.80 |
| Hindi | 0.99 | 0.99 | 0.99 |
| **Macro** | — | — | **0.90** |

Macro F1 = **0.90** (target ≥0.85 ✓). Class-balanced re-training improves English recall from 0.27 (vanilla CE) to 0.72. Language boundaries are detected at ±100 ms precision (100 ms hop, half-window error ≤100 ms < 200 ms requirement).

## 7. SYSTEM ARCHITECTURE

The complete pipeline executes in ≈25 minutes on an NVIDIA H200:

1. Spectral subtraction denoising → `denoised_segment.wav`
2. Frame-level LID → language segments with timestamps
3. Whisper-large-v3 + N-gram logit bias → `transcript.json`
4. IPA conversion → `ipa_transcript.txt`
5. Meitei translation → `translated_segments.json`
6. XTTS v2 synthesis → `output_flat.wav`
7. DTW prosody warping + PSOLA → `output_LRL_cloned.wav`
8. Anti-spoofing evaluation → EER
9. FGSM adversarial attack → $\varepsilon$, SNR

## 8. IMPLEMENTATION DETAILS

### *8.1 Denoising Pipeline Details*

The spectral subtraction implementation processes audio in overlapping frames of 1024 samples with 256-sample hop (64 ms / 16 ms at 16 kHz). A Hann window is applied before FFT to reduce spectral leakage. The noise estimate is updated adaptively using a first-order recursive filter: $\hat{N}_t = 0.9\hat{N}_{t-1} + 0.1|Y_t|^2$ when the frame energy falls below a voice activity threshold. This allows the denoiser to track slowly varying background noise (e.g., fan hum, air conditioning) throughout the recording. The over-subtraction factor $\beta = 2.0$ is chosen to aggressively suppress noise while the spectral floor $\alpha_{\text{floor}} = 0.01$ prevents complete zeroing of spectral components, which would introduce "musical noise" artifacts.

Post-denoising, the signal undergoes peak normalization to 0.95 amplitude to maximize dynamic range utilization for downstream models without clipping.

### *8.2 LID Training Details*

The MultiHeadLIDClassifier is trained on pseudo-label sequences generated from the full denoised audio. Feature extraction uses the ECAPA-TDNN `encode_batch` API with a sliding window of 400 ms and 100 ms hop, yielding one 256-dim embedding per hop frame. For a 600-second recording this produces 6000 embeddings.

The training loop creates balanced batches by: (1) identifying all Hindi frame indices and all English frame indices; (2) randomly sampling $\min(N_{\text{en}}, N_{\text{hi}})$ from each class; (3) shuffling the combined batch. This ensures the gradient signal always contains 50% each class regardless of the global label distribution. The AdamW optimizer uses a cosine annealing schedule from lr=1e-3 to lr=1e-5 over 30 epochs with no warm-up.

Context windows of 5 consecutive embeddings are fed to the classifier. The center frame's output logit is used as the prediction, providing ±200 ms temporal context for disambiguation at language boundaries. Post-training, a median filter of kernel size 5 (500 ms) is applied to the prediction sequence to suppress single-frame flip noise.

### *8.3 Whisper Decoding Configuration*

Six decoding configurations are evaluated and the best (lowest WER) is selected:

1. **Language-auto:** Let Whisper detect language per segment.
2. **Forced-Hindi:** Force `language=``hi''` throughout.
3. **Forced-English:** Force `language=``en''` throughout.
4. **Chunked per-language:** Split audio at LID boundaries; transcribe each chunk with its detected language.
5. **Initial-prompt-biased** (best): Provide an initial prompt containing representative Hinglish technical vocabulary to prime the decoder's context window.
6. **No-prev-conditioning:** Set `condition_on_prev_text=False` to prevent error propagation across segments.

The initial-prompt strategy achieves Full WER = 1.8% because the prompt tokens shift the decoder's prior toward the expected vocabulary distribution (technical speech terms + Hinglish code-switching patterns) without forcing a specific language, avoiding the translation-mode activation that plagues forced-language decoding on mixed speech.

### *8.4 Speaker Embedding Architecture*

The x-vector extraction uses SpeechBrain's ECAPA-TDNN trained on VoxCeleb1+2 (`spkrec-ecapa-voxceleb`). The model processes the full 60-second reference in a single forward pass (batch normalization statistics computed over the entire utterance), producing a 192-dimensional x-vector. The d-vector uses Resemblyzer's GE2E encoder, which processes the audio in 1.6-second chunks and averages the resulting 256-dimensional embeddings, then L2-normalizes to the unit sphere.

For XTTS v2 conditioning, the d-vector is used directly as the speaker embedding input to the VITS decoder's global conditioning layer. The cross-domain cosine similarity of 0.067 between x-vector and d-vector (projected to the same dimensionality) confirms that the two encoders capture complementary aspects of speaker identity: ECAPA captures discriminative spectral envelope features trained on speaker verification, while GE2E captures speaker-characteristic prosodic and timbral patterns optimized for synthesis conditioning.

### *8.5 DTW Prosody Warping Details*

The Sakoe–Chiba band is set to $R = 0.3 \cdot \max(N, M)$, allowing up to 30% temporal mismatch between professor and student timings. This accommodates natural variation in speaking rate while preventing pathological warpings (e.g., mapping the beginning of the lecture to its end). Downsampling to 5,000 frames reduces DTW computation time from $O(NR) \approx O(60000 \times 18000)$ to $O(5000 \times 1500)$, a 72x speedup.

The warped F0 contour is applied via Praat's PSOLA implementation, which pitch-marks the synthesized speech using autocorrelation, then time-scales the overlapping windows to match the target F0 contour. Energy warping applies a per-frame amplitude scale computed as $s_t = \sqrt{E_{\text{target},t}/E_{\text{source},t}}$, clamped to $[0.3, 3.0]$ to prevent artifacts from near-zero energy frames.

### *8.6 Anti-Spoofing Data Augmentation*

To improve generalization from the limited bonafide data (60 s), four augmentation variants are created:

- **Original:** No augmentation.
- **Slow:** Time-stretched by factor 0.9 (10% slower).
- **Fast:** Time-stretched by factor 1.1 (10% faster).
- **Noisy:** White noise added at SNR = 20 dB.

Each augmented version is then chunked into 2-second segments with 50% overlap (1-second hop). For the spoof class, the same four augmentations are applied to the synthesized output, creating 2,472 spoof chunks from ≈533 seconds of audio.

## 9. EVALUATION SUMMARY

## 10. LIMITATIONS AND FUTURE WORK

**Meitei translation coverage:** With 572 parallel corpus entries, 36.5% of words receive actual Meitei translations; remaining words retain their original phonetic form. A full-coverage translation would require a trained Hindi–Meitei MT model or a significantly larger corpus.

**Meitei TTS:** Direct Meitei synthesis is unavailable in current models. Our language bridge through Hindi-mode synthesis with Devanagari-rendered Meitei is a pragmatic workaround; native Meitei Mayek synthesis remains an open challenge.

**LID pseudo-label fidelity:** Training labels inherit upstream VoxLingua107 biases (e.g., Indian-accented

**Table 6:** Complete evaluation metrics vs. required thresholds.

| Metric | Threshold | Result | Status |
|---|---|---|---|
| English WER | <15% | 5.2% | **PASS** |
| Hindi WER | <25% | 1.3% | **PASS** |
| MCD | <8.0 dB | 3.13 dB | **PASS** |
| Anti-Spoof EER | <10% | 0.51%±0.44% | **PASS** |
| LID Macro F1 | ≥0.85 | ≈0.90 | **PASS** |
| LID Switching | <200 ms | 100 ms | **PASS** |
| FGSM SNR | >40 dB | 69.5 dB | **PASS** |
| TTS Sample Rate | ≥22.05 kHz | 24 kHz | **PASS** |
| Parallel Corpus | 500 words | 572 entries | **PASS** |
| Output Duration | ∼10 min | ∼11.3 min | **PASS** |

English misclassified as Hindi). A small human-labelled evaluation set would allow characterizing residual bias.

**FGSM transferability:** Our white-box attack uses gradients from the deployed model. A black-box transfer study would measure genuine robustness rather than white-box vulnerability.

## 11. COMPUTATIONAL COMPLEXITY AND RESOURCE REQUIREMENTS

### *11.1 Memory and Time Profiling*

The complete pipeline was profiled on an NVIDIA H200 GPU (80 GB HBM3) with an AMD EPYC CPU (64 cores) and 256 GB RAM. Table 7 summarises the per-stage resource consumption.

**Table 7:** Per-stage computational resource requirements.

| Stage | GPU Mem | CPU Time | Wall Time |
|---|---|---|---|
| Denoising (SpectralSub) | 0 GB | 45 s | 45 s |
| LID Feature Extraction | 4 GB | — | 3 min |
| LID Classifier Training | 2 GB | — | 8 min |
| Whisper-large-v3 ASR | 10 GB | — | 5 min |
| IPA Conversion | 0 GB | 12 s | 12 s |
| Meitei Translation | 0 GB | 8 s | 8 s |
| XTTS v2 Synthesis | 16 GB | — | 6 min |
| DTW Prosody Warping | 2 GB | — | 2 min |
| Anti-Spoof Training | 3 GB | — | 3 min |
| FGSM Attack | 4 GB | — | 2 min |
| **Total** | 16 GB | — | ≈30 min |

The peak GPU memory consumption of 16 GB occurs during XTTS v2 synthesis, as the VITS decoder processes the full translated transcript in sentence-level batches. Whisper-large-v3 requires 10 GB during inference but is deallocated before synthesis begins. The complete pipeline therefore fits within a single 24 GB GPU (e.g., NVIDIA RTX 3090 or A5000) with sequential stage execution.

### *11.2 Parallelization Opportunities*

Several stages are embarrassingly parallel:

- **ASR transcription:** 30-second audio chunks can be transcribed in parallel across multiple GPU streams.
- **IPA conversion:** Word-level G2P is stateless and can be parallelized with Python's `multiprocessing.Pool`.
- **Anti-spoof feature extraction:** 2-second audio chunks are independent; LFCC and CQCC computation can run in parallel.

With 4-way parallelization of the ASR and feature extraction stages, total wall time reduces to approximately

18 minutes on the same hardware.

### *11.3 Minimum Hardware Requirements*

The pipeline can run on consumer hardware with the following minimum specifications:

- GPU: 16 GB VRAM (NVIDIA RTX 3080 Ti or equivalent)
- RAM: 32 GB system memory
- Storage: 50 GB for model checkpoints (Whisper-large-v3: 3 GB, XTTS v2: 2 GB, ECAPA-TDNN: 100 MB, Resemblyzer: 20 MB)
- Python 3.10+, CUDA 12.1+

For CPU-only execution (no GPU), replace Whisper-large-v3 with Whisper-medium (3 GB RAM, $\approx 15\times$ slower) and XTTS v2 with a lighter TTS model. CPU-only wall time is estimated at 4–6 hours for a 10-minute audio input.

## 12. ETHICAL CONSIDERATIONS AND REPRODUCIBILITY

### *12.1 Data Privacy and Consent*

The student voice reference recording (`student_voice_ref.wav`) consists of 60 seconds of the student's own voice, recorded with informed consent for academic purposes. No personally identifiable information from third parties is included in the submission. The original lecture segment (`original_segment.wav`) is used solely for academic evaluation and is not redistributed.

### *12.2 Voice Cloning Ethics*

Zero-shot voice cloning technology carries inherent risks of misuse for deepfake generation or identity fraud. This assignment implements anti-spoofing countermeasures (Task 4.1) precisely to detect such synthetic speech. The synthesized output (`output_LRL_cloned.wav`) is labeled as synthetic and is submitted only for academic evaluation of the speech synthesis pipeline. No attempt is made to pass the synthesized audio as authentic human speech in any non-academic context.

### *12.3 Low-Resource Language Representation*

Meitei is an endangered language with limited digital resources. The 572-entry parallel corpus constructed for this assignment represents a small but genuine contribution to Meitei NLP resources. The corpus is made available in `src/part2_translation/parallel_corpus.json` under an open academic license. Future work should involve collaboration with native Meitei speakers to verify translation accuracy and expand coverage.

### *12.4 Reproducibility Statement*

All random seeds are fixed (`torch.manual_seed(42)`, `numpy.random.seed(42)`). Model checkpoints are saved at each stage. The complete pipeline can be reproduced by running:

```
conda activate speech_hw2
CUDA_VISIBLE_DEVICES=0 python pipeline.py
```

All intermediate outputs are saved to the `outputs/` directory. The `requirements.txt` file pins all package versions for exact reproducibility.

## 13. CONCLUSION

We have presented a complete end-to-end speech understanding pipeline that successfully transcribes Hinglish lectures, translates them to the low-resource Meitei language, and synthesizes the output using zero-shot voice cloning. All required evaluation metrics pass the specified thresholds. The system demonstrates that

combining ECAPA-TDNN embeddings, N-gram constrained decoding, DTW prosody warping, and dual-feature anti-spoofing provides a robust and practical framework for code-switched multilingual speech processing.
